

## 1 Notation

The general structure of figure variable below voltages (ICA and IMA system of notation is shown in figure of equivalent):

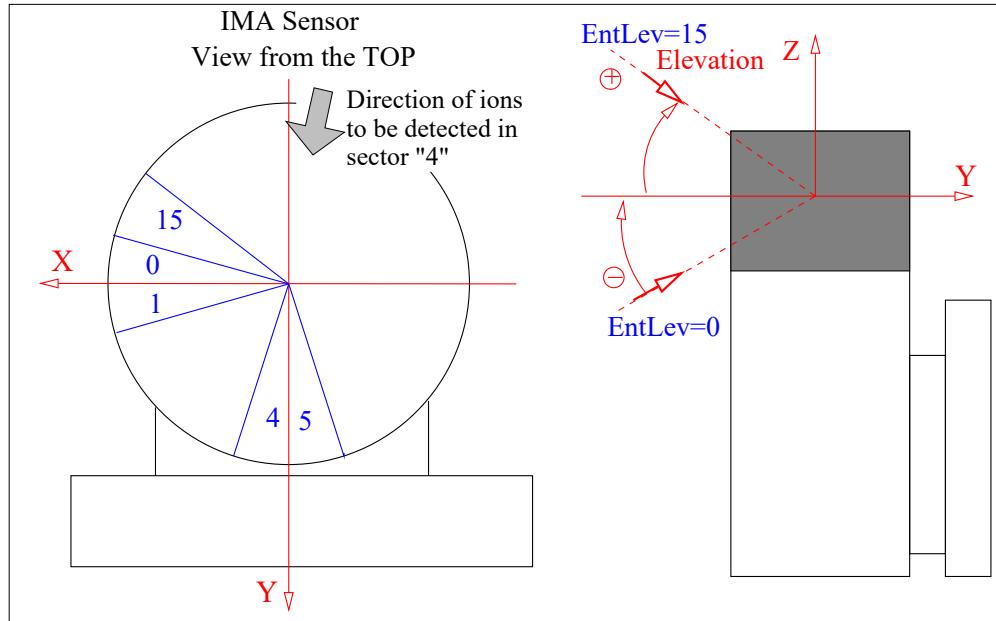

- EAC\_U - voltage of the upper electrode of the scanner; EAC\_ref, and EntU are reference voltage and digital reference respectively.
- EAC\_L is the voltage of low electrode of scanner. It is controlled by the same references.
- ESC\_H - voltage of the inner electrode of spherical analyzer (deflector) ESC\_H\_ref, and DfHV are reference voltage and digital reference respectively.
- ESC\_L - low voltage at the outer electrode of the analyzer and top-hat; DfLV is corresponding digital reference.
- DfL v - number of energy step 0 - 95 (index of deflector voltage)
- EntLev - number of elevation angle 0 - 15 (index of voltage of entrance scanner)
- Pacc - digital reference of post-acceleration 0 - 7
- PacLev - number of PAC level 0 - 2
- LookUpN - number of mass row in the mass look-up table
- M0, M1 - low and high number of the mass rings of given mass spot in the mass look-up table (the interval includes these values). Negative 1 means absence of this mass, or overlapping with more significant mass.

## 2 Coordinate system

The physical location of the azimuthal sectors are shown in the page 2. This figure shows as well the coordinate system used in the present document. In particular the right panel shows the elevation

angles notation. The mass rings in the azimuthal sector is numbered from the center toward periphery. I.e. the very central ring is "0".

### 3 Inputs

1. Energy range of ICA is  $\mathbf{E0} \rightarrow 40000\text{eV/Q}$ . Here  $\mathbf{E0}$  is defined by calibration from the scanner offset. See below. The range is divided into 96 energy steps uniformly in logarithmic scale. The energy less than 100eV/Q is controlled by ESC\_L and energy greater than 100eV/Q is controlled by ESC\_H.

Conversion factor DfHV → ESC\_H\_ref is:

$$ESC\_H\_ref[mV] = -7.531 - 1.168 \cdot DfHV$$

Conversion factor DfLV → ESC\_L is

$$ESC\_L[mV] = 10.140 - 2.728 \cdot DfLV$$

2. Conversion factor EntU → EAC\_ref is:

$$EAC\_ref[mV] = 9.856 + 2.447 \cdot EntU$$

for  $EntU \leq 2047$ , and

$$EAC\_ref[mV] = -10029.4 + 2.451 \cdot EntU$$

for  $EntU > 2047$

3. Post-acceleration levels are chosen as follows:

PACLev	0	1	2
Pacc	0	3	6
RAC_ref[mV]	0.0	1869.0	3740.0

4. Masses resolved by the look-up table are chosen as follows:

LookUpN	0	1	2	3	4	5
Ion	$H^+$	$> O^+$	$O^+$	$He^+$	$He^{++}$	$O^{++}$
M/Q	1	32 (for calculations)	16	4	2	8

(Letter of Hans Nilsson from Feb. 5, 2002)

## 4 Calibration summary

1. In case of  $ESC\_L = 0.0$  the median ion energy is:

$$E/Q[V] = 52.0 - ESC\_H\_ref[mV] \cdot 8.536$$

For low energies if  $ESC\_H\_ref = 0.0$ :

$$E/Q[V] = E_{INT} + ESC\_L[mV] \cdot 10.65 \cdot 10^{-3}$$

Here  $E_{INT}$  is the energy per charge calculated according to  $ESC\_H\_ref$  voltage.

2. The electrostatic scanner is characterized as follows:

$$El^\circ = -2.47 - 189.8 \cdot D + 7.31 \cdot D^2 - 289.2 \cdot D^3$$

here

$$D = \frac{EAC\_ref[mV] - 15.9}{E/Q[V] - 16.0}$$

According to this formula, the minimum ions energy is 16eV/Q. The finite EAC ref resolution and low energy limitation lead to impossibility to register particles less than

$$E_0 = 25\text{eV}/Q$$

energy. The extreme elevation angles are  $-39.0^\circ$  and  $41.0^\circ$ . Dividing this range into 16 levels gives  $5.4^\circ$  angular resolution. FWHM of elevation response is about  $5^\circ$ , thus these two values correspond to each other. EAC HV converter is saturated when  $EAC\_ref < -2920\text{mv}$  and when  $EAC\_ref > 2950\text{mv}$ . This corresponds to  $EntU = 2900$  and  $EntU = 1200$  respectively. See Table notes for more details.

3. Post-acceleration depends on the reference as follows:

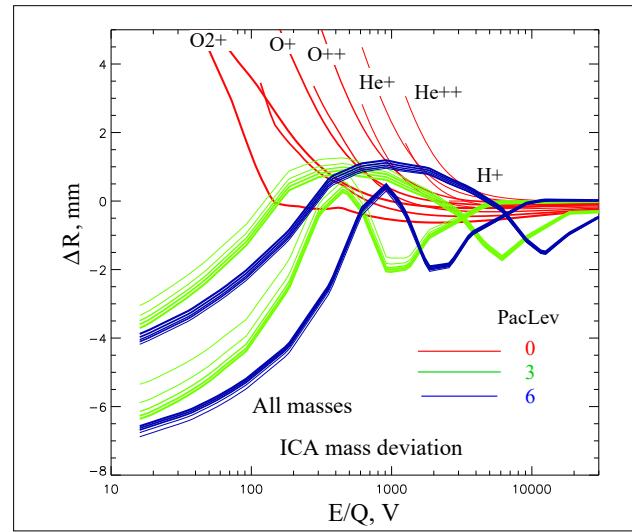

$$PAC[V] = -40.088 + 0.966 \cdot PAC\_ref[mV]$$

Location of the mass-spot boundaries (at the FWHM) on the anode rings is described by:

$$M0 = -6.019 + 2.523 \cdot G - 0.031 \cdot G^2 - \Delta R_{M0}$$

$$M1 = -2.902 + 2.780 \cdot G - 0.043 \cdot G^2 - \Delta R_{M1}$$

Here  $G = \frac{10^3}{\sqrt{(E/Q[V]+PAC[V]) \cdot M/Q}}$ , M is the mass of the particle.  $\Delta R$  is defined by diagram below.

## 5 Tables

Some important notes:

1. Energy steps are enumerated in energy increasing order. DfL v = 0 means minimal energy and DfL v = 95 means maximum energy.
2. Due to the finite EAC\_ref step and due to asymmetry of EAC HV source:
  - (a) For low energy levels just a few randomly distributed angles are available. All available angles are grouped in clusters 2, 4, and 8 Elevation steps to allow make a correct averaging. Repeated EAC\_ref are marked by "\*" to be placed into "unreachable table".
  - (b) For high energy levels some elevations are unreachable. These elevations correspond to EntU greater than 1200 for positive EAC\_ref and less than 2900 for negative EAC\_ref. Target angles which demands unavailable EntU are replaced in table 2 for nearest available values and are marked by \*\*". Thus all bins marked \*\*" should be removed from a processed data stream.
3. For Look-up mass table:
  - (a) M0 - M1 = “-1 - -1” means absence of this mass in the detector range;
  - (b) If low-significant mass (with the greater LookUpN) is overlapped for more than 30% with high-significant mass (with the less LookUpN) the M0 - M1 = “-1 - -1” for the low-significant mass;
  - (c) The lowest M0 is shifted down to 0, and the highest M1 is shifted up to 31 to fill the margin gaps;
  - (d) The M1 of one mass spot and M0 of next mass spot are shifted toward each other to fill the intermediate gap.
4. To simplify the tables installation, each table in the text corresponds to the ASCII file delivered with the present document:
